Cracked teeth represent such a frequent concern to most dentists, because of this the National Dental Practice-Based Research Network has launched a Cracked Tooth Registry study. The overall goal is to identify factors that predict adverse outcomes in cracked teeth.

This will be a four-year observational study of 3,000 cracked teeth nationally. Patients must be 19-85 years old and have a vital posterior permanent natural tooth with a crack (symptomatic or asymptomatic).

You will record an assessment for only one cracked tooth per patient at baseline, and then once each year for four years. If you do any treatment on that tooth, you will also record that information.

Both practitioners and patients will receive compensation for participation within the study.
